

## Description

# Method for forming of tubular work-pieces using a segmented tool

### CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of a U.S. Provisional Application No. 60/481,308, filed on August 29, 2003.

### BACKGROUND OF INVENTION

[0002] The invention relates to the forming of tubular work-pieces by internal pressure created by a fluid, i e hydro-forming, and in particular to a segmented tool used for said forming operation.

[0003] The hydroforming process is described in "Hydroforming – Umformen mit Wirkmedien im Automobilbau, Verlag Moderne Industrie, Landsberg, 2002". In this process tubes formed to final shape by insertion in a tool where the tubes are expanded by applying an internal pressure to the inside of the tube using a fluid. The tubes may be straight or pre-bent depending on the final requirements.

[0004] Hydroforming of large work-pieces, such as side-

members for car body structures presents significant problems due to the difficulty of handling the very heavy tools that are required as moulds during forming. For this reason segmented tool inserts, i e tools that consists of two or more parts, are sometimes used, which considerably facilitates the handling and makes it possible to exchange parts of the inserts if the insert has been damaged or worn, without replacing the whole tool. To keep the segments in place the tool insert is surrounded by a base block, with tight tolerances to the segmented inserts. The base block may be manufactured in one part or may comprise a base and vertical supports fixed to it. The disadvantage of this arrangement is the high cost for the base blocks and the fact that these base blocks are even heavier and more difficult to handle than single piece inserts. The problems connected with the use of large toolings become particularly pronounced when small series or prototypes are manufactured, which means that the tool has to be replaced frequently. The problem is discussed in "Innenhochdruck-Umformen für Karosseriekomponenten, 3. Chemnitzer Karosseriekolloquium, CBC 2002, Verlag Wissenschaftliche Scripten, Zwickau", page 62, where it is suggested that tools for prototypes are manufactured by

forming a cavity directly in a single piece of metal and simplified in the sense that no inserts are used. This does not make handling of the tool easier and no possibility to exchange a part of the tool is possible.

[0005] In "Hydroforming–Umformen mit Wirkmedien im Automobilbau" segmented inserts are mentioned, but always in combination with base blocks that keep the segments from separating during forming.

## **SUMMARY OF INVENTION**

[0006] An object of the present invention is to provide a simplified tool for hydroforming of tubular work-pieces, where the use of very large tooling blocks can be prevented. The invention is particularly useful when small series or prototypes are manufactured.

[0007] According to a first aspect of the present invention a tool comprising a pair of upper and lower tool inserts having open axial ends and defining an elongated cavity there between when said tool inserts are forced together. The upper and/or lower tool inserts are composed of segments that are attached to the upper and a lower base plates by bolts. Retaining elements, such as pins, are introduced into holes in the base plates from where they extend thorough the base plate and continue into cavities

formed in the segmented insert (or extend from the insert into holes in the baseplate). This prevents the insert segments from moving during the forming operation. The retaining elements normally have a round or a conical shape for easier guidance into the cavities and a tight tolerance to the cavities to minimise movement of the segments. In this way the use of base blocks may be omitted.

- [0008] To guide the tool inserts to the desired position on the base plate guide columns are used. The guide columns are attached to the upper base plate and extend through the base plate and the insert. By lowering the upper tool punch vertically towards the lower base plate the guide columns from the upper tool half are introduced into spaces in the lower half of the insert. The guide columns and the retaining elements may also be attached or form part of the inserts and extend through the base plate into theThe retaining elements may act as guide columns, or separate guide columns may be used. The tolerances, however, has to be tight between pin and the hole in the base plate to assure the non-movement of the insert segments.
- [0009] According to a second aspect of the invention the friction force between the base plate and the insert may be high

enough to prevent axial movement of the segments, and in this case the retaining elements may be omitted.

- [0010] A pair of mandrels adjacent the axial open ends of the elongated cavity retain the tubular work-piece in the cavity and forms a sealed closure of the ends of the tubular work-piece. Work-piece material is forced axially inwardly during forming of the work-piece and hydroforming liquid is entered through the mandrel into the work-piece for hydroforming the work-piece into the final shape. The pressurising of the work-piece may be done either before or after the closure of the tool.
- [0011] The method of the present invention allows the elimination of the very large and heavy base blocks that has been a prerequisite in previously used methods. In this way production times may be shortened and the costs reduced.

#### **BRIEF DESCRIPTION OF DRAWINGS**

- [0012] Figure 1 is a plan view of a hydroforming tool according to the prior art.
- [0013] Figure 2 is a plan view of a hydroforming tool according to the invention.

#### **DETAILED DESCRIPTION**

[0014] In figure 1 a segmented tool according to the state of the art is shown. Vertical supports (V) fixed to the base block, prevents movement of the segments.

[0015] Referring to figure 2, a hydroforming tool comprising a base plate (A) and a segmented insert (B), having through holes for guide columns (C) and smaller diameter holes (D) for the retaining elements (pins not shown in figure). The retaining elements are snugly fitted into the base plate, which makes attachment of the elements superfluous. As can be seen the tool is free from vertical supports acting on the outer surface of the insert.

[0016] When the upper tool half is lowered, the guide columns assure the guiding of the tool parts to their exact position. When pressure is applied to the hydroforming liquid, high forces act on the tool parts, some of these in directions that would cause separation of the segments of the inserts if no opposed forces counteract them. The retaining elements or sometimes, depending on the dimension and shape of the workpiece, only the friction force acting between the base plate and segmented inserts caused by the high pressure applied to the tool surfaces, will prevent the separation of the segments. There is thereby no need for vertical supports acting on the outer surfaces of the

insert.

- [0017] The number of segments may be varied freely, it is however common for the number of segments to exceed two.
- [0018] In particular, the invention provides a method of hydro-forming hollow work-pieces by providing a pair of upper and lower tool inserts (B) having open axial ends and defining an elongated cavity (E) there between when said tool inserts are forced together, said upper and/or lower tool inserts being composed of at least two segments that are in a locked position in all directions (X, Y, Z) during the forming of the work-piece and in contact with a base plate (A) on the side opposite to the cavity and
- [0019] ·a) providing a hollow work-piece in said cavity;
- [0020] ·b) sealing the ends of the hollow work-piece;
- [0021] ·c) filling said work-piece with liquid;
- [0022] ·d) applying an internal pressure to the inside of the work-piece by increasing the pressure on said liquid;
- [0023] ·e) moving said upper and lower tool inserts together to deform portions of the work-piece at any time after step a),
- [0024] where the movement of said segments in the X- and the Y-direction is prevented by other means than by using verti-

cal supports acting on the outer surfaces of the inserts.

[0025] *Example 1*

[0026] A hydroforming tool comprising an upper punch, base plates with a pair of upper and lower tool inserts attached to them is used for forming of a tubular work-piece made from extruded aluminium. The inserts have open axial ends and define an elongated cavity between them when the tool is closed. The inserts are each composed of at least two segments that are screwed onto the base plates. Retaining elements are introduced into holes in the base plate and partially through the segments of the inserts. Guide columns extending through and from the base plates are introduced into cavities formed in the segmented inserts when the upper punch is lowered.

[0027] A tubular work-piece was put in said cavity and the upper and lower tool inserts moved together to deform portions of the work-piece. The ends of the tubular work-piece were sealed and the work-piece filled with liquid through an inlet in the mandrels while supplying work-piece material axially inwardly.

[0028] Pressure was then applied to the inside of the work-piece by increasing the pressure on said liquid. The cavities in the base plates have a tight tolerance to the retaining ele-

ments, so that the movement of the segment during forming is as low as possible. The tool was opened and the formed pieces removed. No marks could be found on the work-piece to indicate that a movement of the segments had taken place. When a number of tubes have been formed the tool insert was replaced by removing each segment separately.

[0029] *Example 2*

[0030] A hydroforming tool as in example 1, but without retaining elements, is used for forming a tubular work-piece made from extruded aluminium. The tubular work-piece is put in said cavity and the upper and lower tool inserts are moved together to deform portions of the work-piece while supplying work-piece material axially inwardly. Pressure of 1500 tonnes is applied to the tool parts by the tool punch. Pressure is then applied to the inside of the work-piece by increasing the pressure on said liquid to 1000 bar. The tool is opened and the formed pieces are removed. No movement of the segments could be observed.
